

Midterm 01

Oct 24, 2017.

- (10 pts) The half precision format uses 16 bits to store a binary floating point number of the form $\pm 1.a_1a_2 \cdots a_t \times 2^e$ where $a_j \in \{0, 1\}$, $-14 \leq e \leq 15$. Find t and derive an upper bound for relative error caused by rounding. Express your final answer as a real number, but need not convert it to decimal expression.

Ans:

There are total 30 different exponents ($-14 \leq e \leq 15$).

It takes 5 bits to give 30 or more different exponents ($2^5 = 32$). **(2 pts)**

Total bits = $1 + t + 5 = 16 \Rightarrow t = 10$ **(2 pts)**.

Let $x = \pm 1.a_1a_2 \cdots a_t \cdots \times 2^e$.

If $a_{t+1} = 0$, then $fl_{round}(x) = \pm 1.a_1a_2 \cdots a_t \times 2^e$. A bound for the relative error is

$$\frac{|x - fl_{round}(x)|}{|x|} = \frac{|0.a_{t+1}a_{t+2} \cdots|}{|1.a_1a_2 \cdots a_t a_{t+1} \cdots|} \times 2^{-t} \leq 2^{-(t+1)}. \quad \text{(2 pts)}$$

If $a_{t+1} = 1$, then $fl_{round}(x) = \pm(1.a_1a_2 \cdots a_t + 2^{-t}) \times 2^e$. The upper bound for relative error becomes

$$\frac{|x - fl_{round}(x)|}{|x|} = \frac{|1 - 0.a_{t+1}a_{t+2} \cdots|}{|1.a_1a_2 \cdots a_t a_{t+1} \cdots|} \times 2^{-t} \leq 2^{-(t+1)}. \quad \text{(2 pts)}$$

Therefore, an upper bound for relative error caused by rounding is 2^{-11} **(2 pts)**.

- (10 pts) Given p_0, p_1 and p_2 , the general solution to the recursion formula $p_n = \frac{10}{3}p_{n-1} - 3p_{n-2} + \frac{2}{3}p_{n-3}$ is $p_n = c_11^n + c_22^n + c_3(\frac{1}{3})^n$ (need not show this). Find all $(c_1, c_2, c_3) \neq (0, 0, 0)$ such that the above iteration is unstable in relative error. Explain.

Ans: Relative error = $\left| \frac{e_n}{p_n^{exact}} \right|$. **(3 pts)**

Note that

$$e_n \approx d_11^n + d_22^n + d_3\left(\frac{1}{3}\right)^n$$

d_1, d_2 and d_3 are of $O(\delta)$ **(4 pts)**.

Therefore, relative error = $\frac{O(\delta)1^n + O(\delta)2^n + O(\delta)(\frac{1}{3})^n}{c_11^n + c_22^n + c_3(\frac{1}{3})^n}$. It is stable if and only if $c_2 \neq 0$. **(3 pts)**

- (10 pts) The first few iteration $(p_i, f(p_i))$, $i = 0, 1, 2, 3, 4$ of method of false position for some equation $f(x) = 0$ is given by

$$(0, -2), \quad (3, 1), \quad (2, 2), \quad (1, 1), \quad \left(\frac{2}{3}, \frac{2}{9}\right)$$

Find p_5 (4 digits will do). Explain.

Ans:

$$f(p_1)f(p_0) < 0 \Rightarrow a = p_0, b = p_1$$

$$f(p_2)f(p_0) < 0 \Rightarrow a = p_0, b = p_2$$

$$f(p_3)f(p_0) < 0 \Rightarrow a = p_0, b = p_3$$

$$f(p_4)f(p_0) < 0 \Rightarrow a = p_0, b = p_4$$

(up to here = 4 pts)

$$\Rightarrow p_5 = p_4 - f(p_4) \frac{p_4 - p_0}{f(p_4) - f(p_0)} \text{ (4 pts)} = 0.6 \text{ (2 pts)}.$$

4. (15 pts) Use any method to find a solution of $\sqrt{1 + 0.9x} - \sqrt{1 - 0.8x} = 1.0 \times 10^{-10}$ to 15 correct digits. You need to prevent loss of accuracy. Standard methods only gives you about 5 correct digits (and 1/3 partial credits).

Ans:

Apply the following identity

$$a^2 - b^2 = (a + b)(a - b)$$

that avoids the subtraction of two nearly identical numbers and gives

$$f(x) = \frac{1.7x}{\sqrt{1 + 0.9x} + \sqrt{1 - 0.8x}} - 10^{-10}. \text{ (7 pts)}$$

Then solve $f(x) = 0$ by any numerical method to find the solution

$$x_* \approx 1.17647058823875 \times 10^{-10}. \text{ (8 pts)}$$

5. (10+5 pts) It is known that the unique solution to $f(x) = x + 3 \sin(x) - 0.01 = 0$ is located near $x = 0$.

(a) Find a fixed point iteration that will converge for any $x_0 \in [-\frac{1}{2}, \frac{1}{2}]$. Show that your method satisfies the assumptions of a relevant Theorem, but need not prove the Theorem again. You can use the numerical values of $\sin(\frac{1}{2})$, $\cos(\frac{1}{2})$, $\exp(\frac{1}{2})$, etc. in your proof.

(b) Find an N (need not be optimal) such that $|x_n - x^*| < 10^{-30}$ for all $n \geq N$ with $x_0 = 0$ (assuming a higher precision floating point arithmetic is used).

Ans:

- (a) Direct fixed point iteration with $g(x) = g_0(x) = 0.01 - 3\sin(x)$ does not converge. Instead, a proper choice of β and $g(x) = \beta x + (1-\beta)g_0(x)$ will result in local convergence (**2 pts**). One could choose

$$\beta = \frac{g_0'(\xi)}{g_0'(\xi) - 1}$$

for some ξ near 0. If $\xi = 0$, then $\beta = \frac{3}{4}$. (**2 pts**)

First check $g([-1/2, 1/2]) \subset [-1/2, 1/2]$.

$$-\frac{1}{2} < -0.012931\dots = g(-\frac{1}{2}) \leq g(x) \leq g(\frac{1}{2}) = 0.017931\dots < \frac{1}{2} \quad (\mathbf{3 pts})$$

Second check $|g'(x)| \leq k$ for some $k \in (0, 1)$, $\forall x \in (-1/2, 1/2)$.

$$|g'(x)| = \left| \frac{3}{4}(1 - \cos(x)) \right| \leq \frac{3}{4} < 1 \quad \forall x \in (-\frac{1}{2}, \frac{1}{2}) \quad (\mathbf{3 pts})$$

- (b) Estimation (**3 pts**) Result N (**2 pts**)

[Method 1]

$$|x_n - x_*| \leq k^n \max\{x_0 - a, b - x_0\} = \left(\frac{3}{4}\right)^n \max\left\{0 - \left(-\frac{1}{2}\right), \frac{1}{2} - 0\right\} = \left(\frac{3}{4}\right)^n \frac{1}{2} < 10^{-30}$$

$$\Rightarrow n > \frac{\log_{10} 2 - 30}{\log_{10} \frac{3}{4}} = 237.71\dots \Rightarrow N = 238.$$

[Method 2]

$$|x_n - x_*| \leq \frac{k^n}{1 - k} |x_1 - x_0| = 4 \left(\frac{3}{4}\right)^n |g(0) - 0| = \left(\frac{3}{4}\right)^n 0.01 < 10^{-30}$$

$$\Rightarrow n > \frac{28}{\log_{10} \frac{4}{3}} = 224.11\dots \Rightarrow N = 225.$$

6. (15 pts) Give a cubically convergent method to solve for $e^x - 1 = 0$. Give the formula and prove that it is cubically convergent (locally). If you cannot do it, do the same for a locally quadratically convergent method for partial credit.

Answer:

[Cubic]

One solution is given by (there may be others)

$$x_{n+1} = g(x_n), \quad g(x) = x - \frac{f(x)}{f'(x)} - \frac{f''(x)}{2f'(x)} \left[\frac{f(x)}{f'(x)} \right]^2. \quad (\mathbf{5 pts})$$

Check that $g'(p) = g''(p) = 0$ and $g^{(3)}(p) \neq 0$, and then compute

$$\lim_{n \rightarrow \infty} \frac{|p_{n+1} - p|}{|p_n - p|^3} = \frac{|g^{(3)}(p)|}{3!}. \quad (\mathbf{10 pts})$$

[Quadratic]

$$x_{n+1} = g(x_n), \quad g(x) = x - \frac{f(x)}{f'(x)}. \quad (2 \text{ pts})$$

Check that $g'(p) = 0$ and $g''(p) \neq 0$, and then compute

$$\lim_{n \rightarrow \infty} \frac{|p_{n+1} - p|}{|p_n - p|^2} = \frac{|g''(p)|}{2!}. \quad (5 \text{ pts})$$

7. (10 pts) Derive Aitken's Δ^2 acceleration method.

Hint: the starting point is to assume p_n converges to p linearly.

Ans:

Start from the assumption

$$\frac{p_{n+1} - p}{p_n - p} \approx \frac{p_{n+2} - p}{p_{n+1} - p}.$$

See derivation in the textbook. Partial credits for partial results.

8. (15 pts) Use any method to solve the nonlinear system of equations

$$\sin(x) + \frac{2y}{1+x} = 0.01, \quad 5x + \sin\left(\frac{6y}{1+y^2}\right) = 0.02.$$

Write your answer in the format of 'format long e'.

Hint: the solution is near $(0, 0)$ where $\sin x \approx x$, $\frac{y}{1+x} \approx y$, etc. to leading orders.

Ans:

Let

$$g_1(\mathbf{x}) = \frac{1}{5} \left(0.02 - \sin\left(\frac{6y}{1+y^2}\right) \right)$$
$$g_2(\mathbf{x}) = \frac{1}{2}(0.01 - \sin(x))(1+x)$$

and

$$\mathbf{G}(\mathbf{x}) = (g_1(\mathbf{x}), g_2(\mathbf{x}))^t$$
$$\bar{\mathbf{G}}(\mathbf{x}) = \alpha \mathbf{x} + (I - \alpha)\mathbf{G}(\mathbf{x})$$

where α is a 2×2 matrix and I is the identity matrix. One could choose

$$\alpha = (D\mathbf{G}(\mathbf{x}_0) - I)^{-1}D\mathbf{G}(\mathbf{x}_0).$$

(up to here = 5 pts)

If $\mathbf{x}_0 = (0, 0)^t$, then the iteration gives

$$\mathbf{x}_* \approx (-4.882452175e - 03, 7.404885005e - 03)^t. \quad (10 \text{ pts})$$
